(57) **ABSTRACT**

Methods and devices to detect analyte in body fluid are provided. Embodiments include receiving one or more analyte sensor data, receiving a reference measurement value associated with an analyte level, determining a sensitivity parameter based on the received one or more analyte sensor data and the reference measurement value, performing a probability analysis based on prior analyte sensor data to determine presence of signal attenuation, and generating an output value based on the probability analysis.

METHOD AND DEVICE FOR EARLY SIGNAL ATTENUATION DETECTION USING BLOOD GLUCOSE MEASUREMENTS

RELATED APPLICATIONS

The present application is a continuation of U.S. patent application Ser. No. 13/924,529 filed Jun. 21, 2013, now U.S. Pat. No. 8,676,513, which is a continuation of U.S. patent application Ser. No. 13/356,590 filed Jan. 23, 2012, now U.S. Pat. No. 8,473,220, which is a continuation of U.S. patent application Ser. No. 12/362,475 filed Jan. 29, 2009 now U.S. Pat. No. 8,103,456, entitled "Method and Device for Early Signal Attenuation Detection Using Blood Glucose Measurements", the disclosures of each of which are incorporated herein by reference for all purposes.

BACKGROUND

The detection of the level of glucose or other analytes, such as lactate, oxygen or the like, in certain individuals is vitally important to their health. For example, the monitoring of glucose is particularly important to individuals with diabetes. Diabetics may need to monitor glucose levels to determine when insulin is needed to reduce glucose levels in their bodies or when additional glucose is needed to raise the level of glucose in their bodies.

Devices have been developed for continuous or automatic monitoring of analytes, such as glucose, in bodily fluid such as in the blood stream or in interstitial fluid. Some of these analyte measuring devices are configured so that at least a portion of the devices are positioned below a skin surface of a user, e.g., in a blood vessel or in the subcutaneous tissue of a user.

Following the sensor insertion, the resulting potential trauma to the skin and/or underlying tissue, for example, by the sensor introducer and/or the sensor itself, may, at times, result in instability of signals monitored by the sensor. This may occur in a number of analyte sensors, but not in all cases. This instability is characterized by a decrease in the sensor signal, and when this occurs, generally, the analyte levels monitored may not be reported, recorded or output to the user.

SUMMARY

Embodiments of the subject disclosure include device and methods of determining early signal attenuation (ESA) in signals from analyte sensors. More specifically, embodiments include method, device and system for receiving one or more analyte sensor data, receiving a reference measurement value associated with an analyte level, determining a sensitivity parameter based on the received one or more analyte sensor data and the reference measurement value, performing a probability analysis based on prior analyte sensor data to determine presence of signal attenuation, and generating an output value based on the probability analysis.

Also provided are systems, computer program products, and kits.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows a block diagram of an embodiment of a data monitoring and management system according to the present disclosure;

FIG. 2 shows a block diagram of an embodiment of the transmitter unit of the data monitoring and management system of FIG. 1;

2

FIG. 3 shows a block diagram of an embodiment of the receiver/monitor unit of the data monitoring and management system of FIG. 1;

FIG. 4 shows a schematic diagram of an embodiment of an analyte sensor according to the present disclosure;

FIGS. 5A-5B show a perspective view and a cross sectional view, respectively of an embodiment the analyte sensor of FIG. 4;

FIG. 6 is a flowchart illustrating analyte sensor ESA condition determination in accordance with one aspect of the present disclosure;

FIG. 7 is a flowchart illustrating probability of sensor signal attenuation determination of FIG. 6 in one aspect of the present disclosure;

FIG. 8 is a graph illustrating probability of ESA condition based on prior sensor data in accordance with one aspect of the present disclosure; and

FIG. 9 illustrates probability distribution functions of an analyte sensor in ESA condition and when not in ESA condition based on sensor sensitivity in accordance with one aspect of the present disclosure.

DETAILED DESCRIPTION

Within the scope of the present disclosure, early signal attenuation (ESA) which may be attributable to associated instability of monitored analyte levels resulting from skin and/or tissue trauma when the sensor is transcutaneously positioned under the skin layer of a user may be determined using prior sensor data and analysis based upon the prior data.

Before the present disclosure is described in additional detail, it is to be understood that this disclosure is not limited to particular embodiments described, as such may, of course, vary. It is also to be understood that the terminology used herein is for the purpose of describing particular embodiments only, and is not intended to be limiting, since the scope of the present disclosure will be limited only by the appended claims.

Where a range of values is provided, it is understood that each intervening value, to the tenth of the unit of the lower limit unless the context clearly dictates otherwise, between the upper and lower limit of that range and any other stated or intervening value in that stated range, is encompassed within the disclosure. The upper and lower limits of these smaller ranges may independently be included in the smaller ranges is also encompassed within the disclosure, subject to any specifically excluded limit in the stated range. Where the stated range includes one or both of the limits, ranges excluding either or both of those included limits are also included in the disclosure.

Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this disclosure belongs. Although any methods and materials similar or equivalent to those described herein can also be used in the practice or testing of the present disclosure, the preferred methods and materials are now described. All publications mentioned herein are incorporated herein by reference to disclose and describe the methods and/or materials in connection with which the publications are cited.

It must be noted that as used herein and in the appended claims, the singular forms "a", "an", and "the" include plural referents unless the context clearly dictates otherwise.

The publications discussed herein are provided solely for their disclosure prior to the filing date of the present application. Nothing herein is to be construed as an admission that the present disclosure is not entitled to antedate such publi-

cation by virtue of prior disclosure. Further, the dates of publication provided may be different from the actual publication dates which may need to be independently confirmed.

As will be apparent to those of skill in the art upon reading this disclosure, each of the individual embodiments described and illustrated herein has discrete components and features which may be readily separated from or combined with the features of any of the other several embodiments without departing from the scope or spirit of the present disclosure.

The figures shown herein are not necessarily drawn to scale, with some components and features being exaggerated for clarity.

Generally, embodiments of the present disclosure relate to methods and devices for detecting at least one analyte such as glucose in body fluid. In certain embodiments, the present disclosure relates to the continuous and/or automatic in vivo monitoring of the level of an analyte using an analyte sensor.

Accordingly, embodiments include analyte monitoring devices and systems that include an analyte sensor—at least a portion of which is positionable beneath the skin of the user—for the in vivo detection, of an analyte, such as glucose, lactate, and the like, in a body fluid. Embodiments include wholly implantable analyte sensors and analyte sensors in which only a portion of the sensor is positioned under the skin and a portion of the sensor resides above the skin, e.g., for contact to a transmitter, receiver, transceiver, processor, etc. The sensor may be, for example, subcutaneously positionable in a patient for the continuous or periodic monitoring of a level of an analyte in a patient's interstitial fluid. For the purposes of this description, continuous monitoring and periodic monitoring will be used interchangeably, unless noted otherwise. The analyte level may be correlated and/or converted to analyte levels in blood or other fluids. In certain embodiments, an analyte sensor may be positioned in contact with interstitial fluid to detect the level of glucose, which detected glucose may be used to infer the glucose level in the patient's bloodstream. Analyte sensors may be insertable into a vein, artery, or other portion of the body containing fluid. Embodiments of the analyte sensors of the subject disclosure may be configured for monitoring the level of the analyte over a time period which may range from minutes, hours, days, weeks, or longer.

Of interest are analyte sensors, such as glucose sensors, that are capable of in vivo detection of an analyte for about one hour or more, e.g., about a few hours or more, e.g., about a few days or more, e.g., about three days or more, e.g., about five days or more, e.g., about seven days or more, e.g., about several weeks or at least one month. Future analyte levels may be predicted based on information obtained, e.g., the current analyte level at time t_0 , the rate of change of the analyte, etc. Predictive alarms may notify the user of predicted analyte levels that may be of concern prior in advance of the analyte level reaching the future level. This enables the user an opportunity to take corrective action.

FIG. 1 shows a data monitoring and management system such as, for example, an analyte (e.g., glucose) monitoring system **100** in accordance with certain embodiments. Embodiments of the subject disclosure are further described primarily with respect to glucose monitoring devices and systems, and methods of glucose detection, for convenience only and such description is in no way intended to limit the scope of the disclosure. It is to be understood that the analyte monitoring system may be configured to monitor a variety of analytes at the same time or at different times.

Analytes that may be monitored include, but are not limited to, acetyl choline, amylase, bilirubin, cholesterol, chorionic gonadotropin, creatine kinase (e.g., CK-MB), creatine, DNA,

fructosamine, glucose, glutamine, growth hormones, hormones, ketones, lactate, peroxide, prostate-specific antigen, prothrombin, RNA, thyroid stimulating hormone, and troponin. The concentration of drugs, such as, for example, antibiotics (e.g., gentamicin, vancomycin, and the like), digitoxin, digoxin, drugs of abuse, theophylline, and warfarin, may also be monitored. In those embodiments that monitor more than one analyte, the analytes may be monitored at the same or different times.

The analyte monitoring system **100** includes a sensor **101**, a data processing unit **102** connectable to the sensor **101**, and a primary receiver unit **104** which is configured to communicate with the data processing unit **102** via a communication link **103**. In certain embodiments, the primary receiver unit **104** may be further configured to transmit data to a data processing terminal **105** to evaluate or otherwise process or format data received by the primary receiver unit **104**. The data processing terminal **105** may be configured to receive data directly from the data processing unit **102** via a communication link which may optionally be configured for bi-directional communication. Further, the data processing unit **102** may include a transmitter or a transceiver to transmit and/or receive data to and/or from the primary receiver unit **104**, the data processing terminal **105** or optionally the secondary receiver unit **106**.

Also shown in FIG. 1 is an optional secondary receiver unit **106** which is operatively coupled to the communication link and configured to receive data transmitted from the data processing unit **102**. The secondary receiver unit **106** may be configured to communicate with the primary receiver unit **104**, as well as the data processing terminal **105**. The secondary receiver unit **106** may be configured for bi-directional wireless communication with each of the primary receiver unit **104** and the data processing terminal **105**. As discussed in further detail below, in certain embodiments the secondary receiver unit **106** may be a de-featured receiver as compared to the primary receiver, i.e., the secondary receiver may include a limited or minimal number of functions and features as compared with the primary receiver unit **104**. As such, the secondary receiver unit **106** may include a smaller (in one or more, including all, dimensions), compact housing or embodied in a device such as a wrist watch, arm band, etc., for example. Alternatively, the secondary receiver unit **106** may be configured with the same or substantially similar functions and features as the primary receiver unit **104**. The secondary receiver unit **106** may include a docking portion to be mated with a docking cradle unit for placement by, e.g., the bedside for night time monitoring, and/or bi-directional communication device.

Only one sensor **101**, data processing unit **102** and data processing terminal **105** are shown in the embodiment of the analyte monitoring system **100** illustrated in FIG. 1. However, it will be appreciated by one of ordinary skill in the art that the analyte monitoring system **100** may include more than one sensor **101** and/or more than one data processing unit **102**, and/or more than one data processing terminal **105**. Multiple sensors may be positioned in a patient for analyte monitoring at the same or different times. In certain embodiments, analyte information obtained by a first positioned sensor may be employed as a comparison to analyte information obtained by a second sensor. This may be useful to confirm or validate analyte information obtained from one or both of the sensors. Such redundancy may be useful if analyte information is contemplated in critical therapy-related decisions. In certain embodiments, a first sensor may be used to calibrate a second sensor.

5

The analyte monitoring system **100** may be a continuous monitoring system, or semi-continuous, or a discrete monitoring system. In a multi-component environment, each component may be configured to be uniquely identified by one or more of the other components in the system so that communication conflict may be readily resolved between the various components within the analyte monitoring system **100**. For example, unique IDs, communication channels, and the like, may be used.

In certain embodiments, the sensor **101** is physically positioned in or on the body of a user whose analyte level is being monitored. The sensor **101** may be configured to at least periodically sample the analyte level of the user and convert the sampled analyte level into a corresponding signal for transmission by the data processing unit **102**. The data processing unit **102** is coupleable to the sensor **101** so that both devices are positioned in or on the user's body, with at least a portion of the analyte sensor **101** positioned transcutaneously. The data processing unit **102** performs data processing functions, where such functions may include but are not limited to, filtering and encoding of data signals, each of which corresponds to a sampled analyte level of the user, for transmission to the primary receiver unit **104** via the communication link **103**. In one embodiment, the sensor **101** or the data processing unit **102** or a combined sensor/data processing unit may be wholly implantable under the skin layer of the user.

In one aspect, the primary receiver unit **104** may include an analog interface section including an RF receiver and an antenna that is configured to communicate with the data processing unit **102** via the communication link **103**, data processing unit **102** and a data processing section for processing the received data from the data processing unit **102** such as data decoding, error detection and correction, data clock generation, and/or data bit recovery.

In operation, the primary receiver unit **104** in certain embodiments is configured to synchronize with the data processing unit **102** to uniquely identify the data processing unit **102**, based on, for example, an identification information of the data processing unit **102**, and thereafter, to periodically receive signals transmitted from the data processing unit **102** associated with the monitored analyte levels detected by the sensor **101**.

Referring again to FIG. **1**, the data processing terminal **105** may include a personal computer, a portable computer such as a laptop or a handheld device (e.g., personal digital assistants (PDAs), telephone such as a cellular phone (e.g., a multimedia and Internet-enabled mobile phone such as an iPhone or similar phone), mp3 player, pager, and the like), drug delivery device, each of which may be configured for data communication with the receiver via a wired or a wireless connection. Additionally, the data processing terminal **105** may further be connected to a data network (not shown) for storing, retrieving, updating, and/or analyzing data corresponding to the detected analyte level of the user.

The data processing terminal **105** may include an infusion device such as an insulin infusion pump or the like, which may be configured to administer insulin to patients, and which may be configured to communicate with the primary receiver unit **104** for receiving, among others, the measured analyte level. Alternatively, the primary receiver unit **104** may be configured to integrate an infusion device therein so that the primary receiver unit **104** is configured to administer insulin (or other appropriate drug) therapy to patients, for example, for administering and modifying basal profiles, as well as for determining appropriate boluses for administration based on, among others, the detected analyte levels

6

received from the data processing unit **102**. An infusion device may be an external device or an internal device (wholly implantable in a user).

In particular embodiments, the data processing terminal **105**, which may include an insulin pump, may be configured to receive the analyte signals from the data processing unit **102**, and thus, incorporate the functions of the primary receiver unit **104** including data processing for managing the patient's insulin therapy and analyte monitoring. In certain embodiments, the communication link **103** as well as one or more of the other communication interfaces shown in FIG. **1** may use one or more of an RF communication protocol, an infrared communication protocol, a Bluetooth® enabled communication protocol, an 802.11x wireless communication protocol, or an equivalent wireless communication protocol which would allow secure, wireless communication of several units (for example, per HIPAA requirements) while avoiding potential data collision and interference.

FIG. **2** is a block diagram of the data processing unit of the data monitoring and detection system shown in FIG. **1** in accordance with certain embodiments. The data processing unit **102** thus may include one or more of an analog interface **201** configured to communicate with the sensor **101** (FIG. **1**), a user input **202**, and a temperature detection section **203**, each of which is operatively coupled to a transmitter processor **204** such as a central processing unit (CPU). The transmitter may include user input and/or interface components or may be free of user input and/or interface components.

Further shown in FIG. **2** are serial communication section **205** and an RF transmitter **206**, each of which is also operatively coupled to the transmitter processor **204**. Moreover, a power supply **207**, such as a battery, may also be provided in the data processing unit **102** to provide the necessary power for the data processing unit **102**. Additionally, as can be seen from the Figure, clock **208** may be provided to, among others, supply real time information to the transmitter processor **204**.

As can be seen in the embodiment of FIG. **2**, the sensor unit **101** (FIG. **1**) includes four contacts, three of which are electrodes—work electrode (W) **210**, guard contact (G) **211**, reference electrode (R) **212**, and counter electrode (C) **213**, each operatively coupled to the analog interface **201** of the data processing unit **102**. In certain embodiments, each of the work electrode (W) **210**, guard contact (G) **211**, reference electrode (R) **212**, and counter electrode (C) **213** may be made using a conductive material that may be applied by, e.g., chemical vapor deposition (CVD), physical vapor deposition, sputtering, reactive sputtering, printing, coating, ablating (e.g., laser ablation), painting, dip coating, etching, and the like. Materials include but are not limited to aluminum, carbon (such as graphite), cobalt, copper, gallium, gold, indium, iridium, iron, lead, magnesium, mercury (as an amalgam), nickel, niobium, osmium, palladium, platinum, rhenium, rhodium, selenium, silicon (e.g., doped polycrystalline silicon), silver, tantalum, tin, titanium, tungsten, uranium, vanadium, zinc, zirconium, mixtures thereof, and alloys, oxides, or metallic compounds of these elements.

The processor **204** may be configured to generate and/or process control signals to the various sections of the data processing unit **102** during the operation of the data processing unit **102**. In certain embodiments, the processor **204** also includes memory (not shown) for storing data such as the identification information for the data processing unit **102**, as well as the data associated with signals received from the sensor **101**. The stored information may be retrieved and processed for transmission to the primary receiver unit **104**

under the control of the processor **204**. Furthermore, the power supply **207** may include a commercially available battery.

In certain embodiments, a manufacturing process of the data processing unit **102** may place the data processing unit **102** in the lower power, non-operating state (i.e., post-manufacture sleep mode). In this manner, the shelf life of the data processing unit **102** may be significantly improved. Moreover, as shown in FIG. 2, while the power supply unit **207** is shown as coupled to the processor **204**, and as such, the processor **204** is configured to provide control of the power supply unit **207**, it should be noted that within the scope of the present disclosure, the power supply unit **207** is configured to provide the necessary power to each of the components of the data processing unit **102** shown in FIG. 2.

Referring yet again to FIG. 2, the power supply section **207** of the data processing unit **102** in one embodiment may include a rechargeable battery unit that may be recharged by a separate power supply recharging unit (for example, provided in the receiver unit **104**) so that the data processing unit **102** may be powered for a longer period of usage time. In certain embodiments, the data processing unit **102** may be configured without a battery in the power supply section **207**, in which case the data processing unit **102** may be configured to receive power from an external power supply source (for example, a battery, electrical outlet, etc.) as discussed in further detail below.

Referring yet again to FIG. 2, a temperature detection section **203** of the data processing unit **102** is configured to monitor the temperature of the skin near the sensor insertion site. The temperature reading may be used to adjust the analyte readings obtained from the analog interface **201**. Also shown is a leak detection circuit **214** coupled to the guard trace (G) **211** and the processor **204** in the data processing unit **102** of the data monitoring and management system **100**. The leak detection circuit **214** may be configured to detect leakage current in the sensor **101** to determine whether the measured sensor data are corrupt or whether the measured data from the sensor **101** is accurate. Such detection may trigger a notification to the user.

FIG. 3 is a block diagram of the receiver/monitor unit such as the primary receiver unit **104** of the data monitoring and management system shown in FIG. 1 in accordance with certain embodiments. The primary receiver unit **104** includes one or more of: a blood glucose test strip interface **301**, an RF receiver **302**, an input **303**, a temperature detection section **304**, and a clock **305**, each of which is operatively coupled to a processing and storage section **307**. The primary receiver unit **104** also includes a power supply **306** operatively coupled to a power conversion and monitoring section **308**. Further, the power conversion and monitoring section **308** is also coupled to the receiver processor **307**. Moreover, also shown are a receiver serial communication section **309**, and an output **310**, each operatively coupled to the processing and storage unit **307**. The receiver may include user input and/or interface components or may be free of user input and/or interface components.

In certain embodiments, the test strip interface **301** includes a glucose level testing portion to receive a blood (or other body fluid sample) glucose test or information related thereto. For example, the interface may include a test strip port to receive a glucose test strip. The device may determine the glucose level of the test strip, and optionally display (or otherwise notice) the glucose level on the output **310** of the primary receiver unit **104**. Any suitable test strip may be employed, e.g., test strips that only require a very small amount (e.g., one microliter or less, e.g., 0.5 microliter or less,

e.g., 0.1 microliter or less), of applied sample to the strip in order to obtain accurate glucose information, e.g. FreeStyle® blood glucose test strips from Abbott Diabetes Care, Inc. Glucose information obtained by the in vitro glucose testing device may be used for a variety of purposes, computations, etc. For example, the information may be used to calibrate sensor **101**, confirm results of the sensor **101** to increase the confidence thereof (e.g., in instances in which information obtained by sensor **101** is employed in therapy related decisions), etc.

In one aspect, the RF receiver **302** is configured to communicate, via the communication link **103** (FIG. 1) with the RF transmitter **206** of the data processing unit **102**, to receive encoded data from the data processing unit **102** for, among others, signal mixing, demodulation, and other data processing. The input **303** of the primary receiver unit **104** is configured to allow the user to enter information into the primary receiver unit **104** as needed. In one aspect, the input **303** may include keys of a keypad, a touch-sensitive screen, and/or a voice-activated input command unit, and the like. The temperature monitor section **304** may be configured to provide temperature information of the primary receiver unit **104** to the processing and control section **307**, while the clock **305** provides, among others, real time or clock information to the processing and storage section **307**.

Each of the various components of the primary receiver unit **104** shown in FIG. 3 is powered by the power supply **306** (or other power supply) which, in certain embodiments, includes a battery. Furthermore, the power conversion and monitoring section **308** is configured to monitor the power usage by the various components in the primary receiver unit **104** for effective power management and may alert the user, for example, in the event of power usage which renders the primary receiver unit **104** in sub-optimal operating conditions. The serial communication section **309** in the primary receiver unit **104** is configured to provide a bi-directional communication path from the testing and/or manufacturing equipment for, among others, initialization, testing, and configuration of the primary receiver unit **104**. Serial communication section **309** can also be used to upload data to a computer, such as time-stamped blood glucose data. The communication link with an external device (not shown) can be made, for example, by cable (such as USB or serial cable), infrared (IR) or RF link. The output/display **310** of the primary receiver unit **104** is configured to provide, among others, a graphical user interface (GUI), and may include a liquid crystal display (LCD) for displaying information. Additionally, the output/display **310** may also include an integrated speaker for outputting audible signals as well as to provide vibration output as commonly found in handheld electronic devices, such as mobile telephones, pagers, etc. In certain embodiments, the primary receiver unit **104** also includes an electro-luminescent lamp configured to provide backlighting to the output **310** for output visual display in dark ambient surroundings.

Referring back to FIG. 3, the primary receiver unit **104** may also include a storage section such as a programmable, non-volatile memory device as part of the processor **307**, or provided separately in the primary receiver unit **104**, operatively coupled to the processor **307**. The processor **307** may be configured to perform Manchester decoding (or other protocol(s)) as well as error detection and correction upon the encoded data received from the data processing unit **102** via the communication link **103**.

In further embodiments, the data processing unit **102** and/or the primary receiver unit **104** and/or the secondary receiver unit **106**, and/or the data processing terminal/infusion section

105 may be configured to receive the blood glucose value wirelessly over a communication link from, for example, a blood glucose meter. In further embodiments, a user manipulating or using the analyte monitoring system **100** (FIG. **1**) may manually input the blood glucose value using, for example, a user interface (for example, a keyboard, keypad, voice commands, and the like) incorporated in the one or more of the data processing unit **102**, the primary receiver unit **104**, secondary receiver unit **106**, or the data processing terminal/infusion section **105**.

Additional detailed descriptions of embodiments of the continuous analyte monitoring system, embodiments of its various components are provided in U.S. Pat. No. 6,175,752 issued Jan. 16, 2001 entitled "Analyte Monitoring Device and Methods of Use", and in application Ser. No. 10/745,878 filed Dec. 26, 2003 entitled "Continuous Glucose Monitoring System and Methods of Use", each assigned to the Assignee of the present application, and the disclosure of each of which are incorporated herein by reference for all purposes.

FIG. **4** schematically shows an embodiment of an analyte sensor in accordance with the present disclosure. The sensor **400** includes electrodes **401**, **402** and **403** on a base **404**. The sensor may be wholly implantable in a user or may be configured so that only a portion is positioned within (internal) a user and another portion outside (external) a user. For example, the sensor **400** may include a portion positionable above a surface of the skin **410**, and a portion positioned below the skin. In such embodiments, the external portion may include contacts (connected to respective electrodes of the second portion by traces) to connect to another device also external to the user such as a transmitter unit. While the embodiment of FIG. **4** shows three electrodes side-by-side on the same surface of base **404**, other configurations are contemplated, e.g., fewer or greater electrodes, some or all electrodes on different surfaces of the base or present on another base, some or all electrodes stacked together, electrodes of differing materials and dimensions, etc.

FIG. **5A** shows a perspective view of an embodiment of an electrochemical analyte sensor **500** having a first portion (which in this embodiment may be characterized as a major portion) positionable above a surface of the skin **510**, and a second portion (which in this embodiment may be characterized as a minor portion) that includes an insertion tip **530** positionable below the skin, e.g., penetrating through the skin and into, e.g., the subcutaneous space **520**, in contact with the user's biofluid such as interstitial fluid. Contact portions of a working electrode **501**, a reference electrode **502**, and a counter electrode **503** are positioned on the portion of the sensor **500** situated above the skin surface **510**. Working electrode **501**, a reference electrode **502**, and a counter electrode **503** are shown at the second section and particularly at the insertion tip **530**. Traces may be provided from the electrode at the tip to the contact, as shown in FIG. **5A**. It is to be understood that greater or fewer electrodes may be provided on a sensor. For example, a sensor may include more than one working electrode and/or the counter and reference electrodes may be a single counter/reference electrode, etc.

FIG. **5B** shows a cross sectional view of a portion of the sensor **500** of FIG. **5A**. The electrodes **501**, **502** and **503**, of the sensor **500** as well as the substrate and the dielectric layers are provided in a layered configuration or construction. For example, as shown in FIG. **5B**, in one aspect, the sensor **500** (such as the sensor unit **101** FIG. **1**), includes a substrate layer **504**, and a first conducting layer **501** such as carbon, gold, etc., disposed on at least a portion of the substrate layer **504**,

and which may provide the working electrode. Also shown disposed on at least a portion of the first conducting layer **501** is a sensing layer **508**.

Referring back to FIG. **5B**, a first insulation layer such as a first dielectric layer **505** is disposed or layered on at least a portion of the first conducting layer **501**, and further, a second conducting layer **509** may be disposed or stacked on top of at least a portion of the first insulation layer (or dielectric layer) **505**. As shown in FIG. **5B**, the second conducting layer **509** may provide the reference electrode **502**, and in one aspect, may include a layer of silver/silver chloride (Ag/AgCl), gold, etc.

Referring still again to FIG. **5B**, a second insulation layer **506** such as a dielectric layer in one embodiment may be disposed or layered on at least a portion of the second conducting layer **509**. Further, a third conducting layer **503** may provide the counter electrode **503**. It may be disposed on at least a portion of the second insulation layer **506**. Finally, a third insulation layer may be disposed or layered on at least a portion of the third conducting layer **503**. In this manner, the sensor **500** may be layered such that at least a portion of each of the conducting layers is separated by a respective insulation layer (for example, a dielectric layer).

The embodiment of FIGS. **5A** and **5B** show the layers having different lengths. Some or all of the layers may have the same or different lengths and/or widths.

In certain embodiments, some or all of the electrodes **501**, **502**, **503** may be provided on the same side of the substrate **504** in the layered construction as described above, or alternatively, may be provided in a co-planar manner such that two or more electrodes may be positioned on the same plane (e.g., side-by side (e.g., parallel) or angled relative to each other) on the substrate **504**. For example, co-planar electrodes may include a suitable spacing there between and/or include dielectric material or insulation material disposed between the conducting layers/electrodes. Furthermore, in certain embodiments one or more of the electrodes **501**, **502**, **503** may be disposed on opposing sides of the substrate **504**. In such embodiments, contact pads may be on the same or different sides of the substrate. For example, an electrode may be on a first side and its respective contact may be on a second side, e.g., a trace connecting the electrode and the contact may traverse through the substrate.

In certain embodiments, the data processing unit **102** may be configured to perform sensor insertion detection and data quality analysis, information pertaining to which may also be transmitted to the primary receiver unit **104** periodically at the predetermined time interval. In turn, the receiver unit **104** may be configured to perform, for example, skin temperature compensation/correction as well as calibration of the sensor data received from the data processing unit **102**.

As noted above, analyte sensors may include an analyte-responsive enzyme in a sensing layer. Some analytes, such as oxygen, can be directly electrooxidized or electroreduced on a sensor, and more specifically at least on a working electrode of a sensor. Other analytes, such as glucose and lactate, require the presence of at least one electron transfer agent and/or at least one catalyst to facilitate the electrooxidation or electroreduction of the analyte. Catalysts may also be used for those analytes, such as oxygen, that can be directly electrooxidized or electroreduced on the working electrode. For these analytes, each working electrode includes a sensing layer (see for example sensing layer **508** of FIG. **5B**) formed proximate to or on a surface of a working electrode. In many embodiments, a sensing layer is formed near or on only a small portion of at least a working electrode.

A variety of different sensing layer configurations may be used. In certain embodiments, the sensing layer is deposited on the conductive material of a working electrode. The sensing layer may extend beyond the conductive material of the working electrode. In some cases, the sensing layer may also extend over other electrodes, e.g., over the counter electrode and/or reference electrode (or counter/reference is provided). The sensing layer may be integral with the material of an electrode.

A sensing layer that is in direct contact with the working electrode may contain an electron transfer agent to transfer electrons directly or indirectly between the analyte and the working electrode, and/or a catalyst to facilitate a reaction of the analyte.

A sensing layer that is not in direct contact with the working electrode may include a catalyst that facilitates a reaction of the analyte. However, such sensing layers may not include an electron transfer agent that transfers electrons directly from the working electrode to the analyte, as the sensing layer is spaced apart from the working electrode. One example of this type of sensor is a glucose or lactate sensor which includes an enzyme (e.g., glucose oxidase, glucose dehydrogenase, lactate oxidase, and the like) in the sensing layer. The glucose or lactate may react with a second compound in the presence of the enzyme. The second compound may then be electrooxidized or electroreduced at the electrode. Changes in the signal at the electrode indicate changes in the level of the second compound in the fluid and are proportional to changes in glucose or lactate level and, thus, correlate to the analyte level.

In certain embodiments which include more than one working electrode, one or more of the working electrodes do not have a corresponding sensing layer, or have a sensing layer which does not contain one or more components (e.g., an electron transfer agent and/or catalyst) needed to electrolyze the analyte. Thus, the signal at this working electrode corresponds to background signal which may be removed from the analyte signal obtained from one or more other working electrodes that are associated with fully-functional sensing layers by, for example, subtracting the signal.

In certain embodiments, the sensing layer includes one or more electron transfer agents. Electron transfer agents that may be employed are electroreducible and electrooxidizable ions or molecules having redox potentials that are a few hundred millivolts above or below the redox potential of the standard calomel electrode (SCE). The electron transfer agent may be organic, organometallic, or inorganic.

In certain embodiments, electron transfer agents have structures or charges which prevent or substantially reduce the diffusional loss of the electron transfer agent during the period of time that the sample is being analyzed. For example, electron transfer agents include but are not limited to a redox species, e.g., bound to a polymer which can in turn be disposed on or near the working electrode. The bond between the redox species and the polymer may be covalent, coordinative, or ionic. Although any organic or organometallic redox species may be bound to a polymer and used as an electron transfer agent, in certain embodiments the redox species is a transition metal compound or complex, e.g., osmium, ruthenium, iron, and cobalt compounds or complexes. It will be recognized that many redox species described for use with a polymeric component may also be used, without a polymeric component.

One type of polymeric electron transfer agent contains a redox species covalently bound in a polymeric composition. An example of this type of mediator is poly(vinylferrocene). Another type of electron transfer agent contains an ionically-

bound redox species. This type of mediator may include a charged polymer coupled to an oppositely charged redox species. Examples of this type of mediator include a negatively charged polymer coupled to a positively charged redox species such as an osmium or ruthenium polypyridyl cation. Another example of an ionically-bound mediator is a positively charged polymer such as quaternized poly(4-vinyl pyridine) or poly(1-vinyl imidazole) coupled to a negatively charged redox species such as ferricyanide or ferrocyanide. In other embodiments, electron transfer agents include a redox species coordinatively bound to a polymer. For example, the mediator may be formed by coordination of an osmium or cobalt 2,2'-bipyridyl complex to poly(1-vinyl imidazole) or poly(4-vinyl pyridine).

Suitable electron transfer agents are osmium transition metal complexes with one or more ligands, each ligand having a nitrogen-containing heterocycle such as 2,2'-bipyridine, 1,10-phenanthroline, or derivatives thereof. The electron transfer agents may also have one or more ligands covalently bound in a polymer, each ligand having at least one nitrogen-containing heterocycle, such as pyridine, imidazole, or derivatives thereof. The present disclosure may employ electron transfer agents have a redox potential ranging from about -100 mV to about +150 mV versus the standard calomel electrode (SCE), e.g., ranges from about -100 mV to about +150 mV, e.g., ranges from about -50 mV to about +50 mV, e.g., electron transfer agents have osmium redox centers and a redox potential ranging from +50 mV to -150 mV versus SCE.

The sensing layer may also include a catalyst which is capable of catalyzing a reaction of the analyte. The catalyst may also, in some embodiments, act as an electron transfer agent. One example of a suitable catalyst is an enzyme which catalyzes a reaction of the analyte. For example, a catalyst, such as a glucose oxidase, glucose dehydrogenase (e.g., pyrroloquinoline quinone glucose dehydrogenase (PQQ)), or oligosaccharide dehydrogenase, may be used when the analyte of interest is glucose. A lactate oxidase or lactate dehydrogenase may be used when the analyte of interest is lactate. Laccase may be used when the analyte of interest is oxygen or when oxygen is generated or consumed in response to a reaction of the analyte.

In certain embodiments, a catalyst may be attached to a polymer, cross linking the catalyst with another electron transfer agent (which, as described above, may be polymeric). A second catalyst may also be used in certain embodiments. This second catalyst may be used to catalyze a reaction of a product compound resulting from the catalyzed reaction of the analyte. The second catalyst may operate with an electron transfer agent to electrolyze the product compound to generate a signal at the working electrode. Alternatively, a second catalyst may be provided in an interferent-eliminating layer to catalyze reactions that remove interferents.

Certain embodiments include a Wired Enzyme™ sensing layer that works at a gentle oxidizing potential, e.g., a potential of about +40 mV. This sensing layer uses an osmium (Os)-based mediator designed for low potential operation and is stably anchored in a polymeric layer. Accordingly, in certain embodiments the sensing element is a redox active component that includes (1) Osmium-based mediator molecules attached by stable (bidentate) ligands anchored to a polymeric backbone, and (2) glucose oxidase enzyme molecules. These two constituents are crosslinked together.

A mass transport limiting layer (not shown), e.g., an analyte flux modulating layer, may be included with the sensor to act as a diffusion-limiting barrier to reduce the rate of mass transport of the analyte, for example, glucose or lactate, into

the region around the working electrodes. The mass transport limiting layers are useful in limiting the flux of an analyte to a working electrode in an electrochemical sensor so that the sensor is linearly responsive over a large range of analyte concentrations and is easily calibrated. Mass transport limiting layers may include polymers and may be biocompatible. A mass transport limiting layer may serve many functions, e.g., functionalities of a biocompatible layer and/or interferent-eliminating layer may be provided by the mass transport limiting layer.

In certain embodiments, a mass transport limiting layer is a membrane composed of crosslinked polymers containing heterocyclic nitrogen groups, such as polymers of polyvinylpyridine and polyvinylimidazole. Electrochemical sensors equipped with such membranes have considerable sensitivity and stability, and a large signal-to-noise ratio, in a variety of conditions.

According to certain embodiments, a membrane is formed by crosslinking in situ a polymer, modified with a zwitterionic moiety, a non-pyridine copolymer component, and optionally another moiety that is either hydrophilic or hydrophobic, and/or has other desirable properties, in an alcohol-buffer solution. The modified polymer may be made from a precursor polymer containing heterocyclic nitrogen groups. Optionally, hydrophilic or hydrophobic modifiers may be used to "fine-tune" the permeability of the resulting membrane to an analyte of interest. Optional hydrophilic modifiers, such as poly(ethylene glycol), hydroxyl or polyhydroxyl modifiers, may be used to enhance the biocompatibility of the polymer or the resulting membrane.

A biocompatible layer (not shown) may be provided over at least that portion of the sensor which is subcutaneously inserted into the patient. The biocompatible layer may be incorporated in the interferent-eliminating layer or in the mass transport limiting layer or may be a separate layer. The layer may prevent the penetration of large biomolecules into the electrodes. The biocompatible layer may also prevent protein adhesion to the sensor, formation of blood clots, and other undesirable interactions between the sensor and body. For example, a sensor may be completely or partially covered on its exterior with a biocompatible coating.

An interferent-eliminating layer (not shown) may be included in the sensor. The interferent-eliminating layer may be incorporated in the biocompatible layer or in the mass transport limiting layer or may be a separate layer. Interferents are molecules or other species that are electroreduced or electrooxidized at the electrode, either directly or via an electron transfer agent, to produce a false signal. In one embodiment, a film or membrane prevents the penetration of one or more interferents into the region around the working electrode. In many embodiments, this type of interferent-eliminating layer is much less permeable to one or more of the interferents than to the analyte. An interferent-eliminating layer may include ionic components to reduce the permeability of the interferent-eliminating layer to ionic interferents having the same charge as the ionic components. Another example of an interferent-eliminating layer includes a catalyst for catalyzing a reaction which removes interferents.

A sensor may also include an active agent such as an anticlotting and/or antiglycolytic agent(s) disposed on at least a portion of a sensor that is positioned in a user. An anticlotting agent may reduce or eliminate the clotting of blood or other body fluid around the sensor, particularly after insertion of the sensor. Blood clots may foul the sensor or irreducibly reduce the amount of analyte which diffuses into the sensor. Examples of useful anticlotting agents include heparin and tissue plasminogen activator (TPA), as well as other

known anticlotting agents. Embodiments may include an antiglycolytic agent or precursor thereof. The term "antiglycolytic" is used broadly herein to include any substance that at least retards glucose consumption of living cells.

Sensors described herein may be configured to require no system calibration or no user calibration. For example, a sensor may be factory calibrated and need not require further calibrating. In certain embodiments, calibration may be required, but may be done without user intervention, i.e., may be automatic. In those embodiments in which calibration by the user is required, the calibration may be according to a predetermined schedule or may be dynamic, i.e., the time for which may be determined by the system on a real-time basis according to various factors. Calibration may be accomplished using an in vitro test strip or other calibrator, e.g., a small sample test strip such as a test strip that requires less than about 1 microliter of sample (for example FreeStyle® blood glucose monitoring test strips from Abbott Diabetes Care, Inc). For example, test strips that require less than about 1 nanoliter of sample may be used. In certain embodiments, a sensor may be calibrated using only one sample of body fluid per calibration event. For example, a user need only lance a body part one time to obtain sample for a calibration event (e.g., for a test strip), or may lance more than one time within a short period of time if an insufficient volume of sample is obtained firstly. Embodiments include obtaining and using multiple samples of body fluid for a given calibration event, where glucose values of each sample are substantially similar. Data obtained from a given calibration event may be used independently to calibrate or combined with data obtained from previous calibration events, e.g., averaged including weighted averaged, filtered and the like, to calibrate.

An analyte system may include an optional alarm system that, e.g., based on information from a processor, warns the patient of a potentially detrimental condition of the analyte. For example, if glucose is the analyte, an alarm system may warn a user of conditions such as hypoglycemia and/or hyperglycemia and/or impending hypoglycemia, and/or impending hyperglycemia. An alarm system may be triggered when analyte levels reach or exceed a threshold value. An alarm system may also, or alternatively, be activated when the rate of change or acceleration of the rate of change in analyte level increase or decrease, reaches or exceeds a threshold rate or acceleration. For example, in the case of a glucose monitoring system, an alarm system may be activated if the rate of change in glucose concentration exceeds a threshold value which might indicate that a hyperglycemic or hypoglycemic condition is likely to occur. A system may also include system alarms that notify a user of system information such as battery condition, calibration, sensor dislodgment, sensor malfunction, etc. Alarms may be, for example, auditory and/or visual. Other sensory-stimulating alarm systems may be used including alarm systems which heat, cool, vibrate, or produce a mild electrical shock when activated.

The subject disclosure also includes sensors used in sensor-based drug delivery systems. The system may provide a drug to counteract the high or low level of the analyte in response to the signals from one or more sensors. Alternatively, the system may monitor the drug concentration to ensure that the drug remains within a desired therapeutic range. The drug delivery system may include one or more (e.g., two or more) sensors, a transmitter, a receiver/display unit, and a drug administration system. In some cases, some or all components may be integrated in a single unit. The sensor-based drug delivery system may use data from the one or more sensors to provide necessary input for a control algorithm/mechanism to adjust the administration of drugs,

15

e.g., automatically or semi-automatically. As an example, a glucose sensor could be used to control and adjust the administration of insulin from an external or implanted insulin pump.

Referring again to the Figures, the probability determination of whether an analyte sensor is in ESA condition in accordance with one aspect of the present disclosure is described in further detail. More specifically, FIG. 6 is a flowchart illustrating analyte sensor ESA condition determination in accordance with one aspect of the present disclosure. Referring to the Figure, one or more signals related to the analyte level monitored is received from the analyte sensor (610). A reference measurement value is also received (620). For example, the reference measurement value may include the result of a contemporaneously performed blood glucose test using an in vitro blood glucose meter. With the analyte data and the time corresponding reference measurement value, the sensor sensitivity is determined, for example, by determining the ratio of the analyte data and the reference measurement value (630).

Referring back to FIG. 6, the probability of analyte sensor ESA condition is determined based on prior sensor data analysis (640) as discussed in further detail below in conjunction with FIG. 7, and thereafter, the determination of whether the analyte sensor is in ESA condition or not based on the determined probability of sensor signal attenuation is generated (650). In one aspect, as discussed in further detail below, the determination of the probability of sensor ESA condition may be based at least in part on a probability analysis of the sensor data based on previously collected and/or received sensor data (whether from the same or different sensor), and/or based at least in part on the probability of the ESA condition based on the determined sensor sensitivity in view of the probability analysis performed on the previously monitored and/or stored analyte data and associated parameters such as sensor sensitivity.

Referring now to FIG. 7 which is a flowchart illustrating probability of sensor signal attenuation determination of FIG. 6, in one aspect, a current sensor data parameter is compared to prior probability of ESA function (710). For example, with reference to FIG. 8 which illustrates a graph illustrating probability of ESA condition based on historical sensor data, and without any data from the present sensor, it can be seen that the prior probability of being in the ESA condition peaks at approximately 0.28 at 4.5 hours, for example, from sensor insertion or positioning in fluid contact with an analyte. In one aspect, the probability of ESA condition based on past analyte data may be stored in a lookup table in one or more data storage units or memory device in the receiver unit (104/106) (FIG. 1), or in a computer terminal or a remote device that has stored therein the prior sensor data information.

Referring back to FIG. 7, it is also determined, based on the analyte sensor sensitivity determined (FIG. 6), the likelihood of the ESA condition based on the determined sensitivity, for example, by comparing with probability distribution functions (PDFs) which illustrate how likely a sensor with a given sensitivity value is in ESA, or is not in ESA (720). These probability distribution functions may be also derived from historical sensor data, but are used in this analysis only after there is data from the present sensor. More specifically, by way of a non-limiting example, FIG. 9 shows the "not in ESA" sensitivity probability distribution function (PDF) with a peak value of approximately 2, and the "in ESA" sensitivity probability distribution function (PDF) peak at a smaller value of sensitivity, attaining a peak value of approximately 1.75.

16

Referring still again to FIG. 7, the prior probability value (from FIG. 8 or a similar curve), and the likelihood values of being in ESA and of not being in ESA (from FIG. 9 or similar curves), are combined using a predefined rule or relationship, such as based on, for example, Bayes Law (730).

Referring yet still to FIG. 7, with the ESA condition determination (730), the ESA condition determination value is reported (740), and may be compared to a predetermined threshold to conclude or ascertain whether or not the analyte sensor is in ESA condition. For example, in one aspect, the predetermined threshold value may be programmed or configured to be a set value to which is compared the output result of the ESA condition determination value. In the event that the comparison yields the ESA condition determination value exceeding the predetermined threshold value, then the analyte monitoring system 100 (FIG. 1) may be configured (for example, by the receiver unit (104/106)) to confirm the presence of ESA condition for the analyte sensor.

In accordance with embodiments of the present disclosure, the predetermined threshold value may be varied, based at least in part, on the prior analysis of the past sensor data stored and processed, for example, in the receiver unit (104/106). Alternatively, depending upon the sensor parameters (for example, nominal sensor code, manufacturing process, sensing chemistry, and the like), there may be associated therewith a predefined or preset threshold value which may be used to compare and determine whether ESA condition is present.

In this manner, in accordance with embodiments of the present disclosure, analyte sensor early signal attenuation condition may be determined, retrospectively or in real time, based, at least in part on an analysis of the past sensor data over a predetermined time period (for example, 30 days or 50 days), and with sensitivity values available for the sensors, a probability function may be used to determine the presence of ESA condition, for example.

When ESA condition is not determined and/or the sensor reaches the equilibration level within the short time period, then the analyte monitoring system may be configured to request a reference measurement value (e.g., blood glucose value) from the user, for example, a fingerstick in vitro test using a blood glucose meter, to calibrate the sensor signals, and thereafter, report or display to the user the monitored analyte levels. Upon successful calibration, the resulting calibrated analyte levels may be displayed to the user, or otherwise stored or logged in the analyte monitoring system or device and/or transmitted to a remote device or computing terminal for further processing.

When the ESA condition is determined based upon, in part, the probability function described herein, for example, the analyte monitoring system may be configured to alert the user to wait a predetermined time period before providing the reference blood glucose value to provide the sensor to stabilize, or alternatively, the user may be prompted to provide the reference blood glucose value to confirm the presence of the ESA condition.

In one aspect, the scheduled calibration of the analyte sensor may be delayed to provide the sensor additional time period to reach a desired or acceptable stability level. Among other conditions, boundaries may be established to provide the sensor additional time period to reach a predetermined or acceptable stability level before the received analyte sensor signals are calibrated, and thus, provided to the user. In this manner, in one aspect, when it is determined that the transcutaneously positioned sensor has reached an acceptable stability level resulting in the desired or predetermined equilibration level, the analyte monitoring system may display or otherwise accept, output, log, or process the monitored ana-

17

lyte level, substantially in real time, received from the transcutaneously positioned sensor.

In the case where ESA condition or the potential for such signal attenuation is determined, the analyte monitoring system may be configured in one embodiment to perform one or more routines or functions to verify the sensor related signals to confirm the ESA condition, to notify the user to refrain from performing a fingerstick test using a blood glucose meter to provide a reference blood glucose value for calibration, among others.

Accordingly, in one aspect, a method includes receiving one or more analyte sensor data, receiving a reference measurement value associated with an analyte level, determining a sensitivity parameter based on the received one or more analyte sensor data and the reference measurement value, performing a probability analysis based on prior analyte sensor data to determine presence of signal attenuation, and generating an output value based on the probability analysis.

In one embodiment, performing a probability analysis may include determining a sensor signal attenuation profile based on the prior analyte sensor data, where the sensor signal attenuation profile may include a value determined at least in part by a sensor calibration schedule.

The prior analyte sensor data may include data associated with monitored analyte level over a predetermined time period, including approximately 30 days, 50 days, 100 days, or any other suitable time periods from which a basis for data analysis may be performed.

In still another aspect, performing a probability analysis may include determining the presence or the absence of signal attenuation based at least in part on the sensitivity parameter, where the determination may include retrieving one or more parameters associated with signal attenuation associated with the sensitivity parameter.

Another aspect may also include comparing the output value to a predetermined threshold level.

A further aspect may additionally include determining the presence of signal attenuation condition for the analyte sensor based on the comparison, where the predetermined threshold level may be adjustable or modifiable by the system and/or the user.

In still another aspect, performing the probability analysis may include applying a predetermined probability function to the sensitivity parameter.

Further, calibrating the received one or more analyte sensor data based at least in part on the determined sensitivity parameter may be included, and also, displaying the calibrated one or more analyte sensor data to a suitable output device such as a visual display, an auditory output and/or a vibratory or tactile output device or component.

An apparatus in another aspect of the present disclosure includes a data communication interface, one or more processors operatively coupled to the data communication interface, and a memory for storing instructions which, when executed by the one or more processors, causes the one or more processors to receive one or more analyte sensor data, receive a reference measurement value associated with an analyte level, determine a sensitivity parameter based on the received one or more analyte sensor data and the reference measurement value, perform a probability analysis based on prior analyte sensor data to determine presence of signal attenuation, and generate an output value based on the probability analysis.

The memory for storing instructions which, when executed by the one or more processors, may cause the one or more processors to determine a sensor signal attenuation profile based on the prior analyte sensor data, where the sensor signal

18

attenuation profile may include a value determined at least in part by a sensor calibration schedule.

In another aspect, the memory for storing instructions which, when executed by the one or more processors, may cause the one or more processors to determine the presence or the absence of signal attenuation based at least in part on the sensitivity parameter, also, where the memory for storing instructions which, when executed by the one or more processors, may cause the one or more processors to retrieve one or more parameters associated with signal attenuation associated with the sensitivity parameter.

In still another aspect, the memory for storing instructions which, when executed by the one or more processors, may cause the one or more processors to compare the output value to a predetermined threshold level.

Further, the memory for storing instructions which, when executed by the one or more processors, may cause the one or more processors to determine the presence of signal attenuation condition for the analyte sensor based on the comparison, where the predetermined threshold level may be adjustable.

In yet still a further aspect, the memory for storing instructions which, when executed by the one or more processors, may cause the one or more processors to apply a predetermined probability function to the sensitivity parameter.

Moreover, the memory for storing instructions which, when executed by the one or more processors, may cause the one or more processors to calibrate the received one or more analyte sensor data based at least in part on the determined sensitivity parameter.

Also, the apparatus may include an output unit operatively coupled to the one or more processors, where the memory for storing instructions which, when executed by the one or more processors, may cause the one or more processors to output the calibrated one or more analyte sensor data.

In yet a further aspect of the present disclosure, there is provided one or more storage devices having processor readable code embodied thereon, said processor readable code for programming one or more processors to determine signal attenuation condition including receiving one or more analyte sensor data, receiving a reference measurement value associated with an analyte level, determining a sensitivity parameter based on the received one or more analyte sensor data and the reference measurement value, performing a probability analysis based on prior analyte sensor data to determine presence of signal attenuation, and generating an output value based on the probability analysis.

The various processes described above including the processes performed by the data processing unit **102**, receiver unit **104/106** or the data processing terminal/infusion section **105** (FIG. 1) in the software application execution environment in the analyte monitoring system **100** including the processes and routines described in conjunction with FIGS. 6-7, may be embodied as computer programs developed using an object oriented language that allows the modeling of complex systems with modular objects to create abstractions that are representative of real world, physical objects and their interrelationships. The software required to carry out the inventive process, which may be stored in the memory or storage device (not shown) of the data processing unit **102**, receiver unit **104/106** or the data processing terminal/infusion section **105**, may be developed by a person of ordinary skill in the art and may include one or more computer program products.

Various other modifications and alterations in the structure and method of operation of this disclosure will be apparent to those skilled in the art without departing from the scope and

19

spirit of the embodiments of the present disclosure. Although the present disclosure has been described in connection with particular embodiments, it should be understood that the present disclosure as claimed should not be unduly limited to such particular embodiments. It is intended that the following claims define the scope of the present disclosure and that structures and methods within the scope of these claims and their equivalents be covered thereby.

What is claimed is:

1. A method, comprising:
 - determining one or more sensitivity values based on one or more retrieved stored analyte sensor data, one or more received analyte sensor data and one or more reference measurement values;
 - determining a sensitivity parameter of an analyte sensor based on the determined one or more sensitivity values; and
 - performing a probability analysis of the determined sensitivity parameter to determine a presence of a signal attenuation condition of the analyte sensor.
2. The method of claim 1, wherein performing the probability analysis includes determining a sensor signal attenuation profile based on the determined one or more sensitivity values.
3. The method of claim 1, wherein the retrieved stored analyte sensor data includes data associated with a monitored analyte level over a predetermined time period.
4. The method of claim 1, wherein performing the probability analysis includes determining the presence or an absence of the signal attenuation condition based at least in part on the determined sensitivity parameter.
5. The method of claim 4, wherein determining the presence or the absence of the signal attenuation condition includes retrieving one or more parameters associated with signal attenuation associated with the determined sensitivity parameter.
6. The method of claim 1, further including generating an output value based on the probability analysis and comparing the output value to a predetermined threshold level.
7. The method of claim 6, further including determining the presence of the signal attenuation condition of the analyte sensor based on the comparison.
8. The method of claim 6, wherein the predetermined threshold level is adjustable.
9. The method of claim 1, wherein performing the probability analysis further includes applying a probability distribution function to the determined sensitivity parameter.
10. The method of claim 1, wherein the one or more reference measurement values include analyte data associated with a second analyte sensor.
11. The method of claim 1, wherein the one or more reference measurement values are received from a second analyte sensor.
12. An apparatus, comprising:
 - an analyte sensor;
 - a data communication interface;

20

one or more processors operatively coupled to the data communication interface and in signal communication with the analyte sensor; and

a memory for storing instructions which, when executed by the one or more processors, causes the one or more processors to determine one or more sensitivity values based on one or more retrieved stored analyte sensor data, one or more received analyte sensor data and one or more reference measurement values, determine a sensitivity parameter of the analyte sensor based on the determined one or more sensitivity values, and perform a probability analysis of the determined sensitivity parameter to determine a presence of a signal attenuation condition of the analyte sensor.

13. The apparatus of claim 12, wherein the memory for storing instructions which, when executed by the one or more processors, further causes the one or more processors to determine a sensor signal attenuation profile based on the determined one or more sensitivity values to perform the probability analysis.

14. The apparatus of claim 12, wherein the one or more retrieved stored analyte sensor data includes data associated with a monitored analyte level over a predetermined time period.

15. The apparatus of claim 12, wherein the memory for storing instructions which, when executed by the one or more processors, further causes the one or more processors to determine the presence or an absence of the signal attenuation condition based at least in part on the determined sensitivity parameter to perform the probability analysis.

16. The apparatus of claim 15, wherein the memory for storing instructions which, when executed by the one or more processors, further causes the one or more processors to retrieve one or more parameters associated with signal attenuation associated with the determined sensitivity parameter to determine the presence or the absence of the signal attenuation condition.

17. The apparatus of claim 12, wherein the memory for storing instructions which, when executed by the one or more processors, further causes the one or more processors to generate an output value based on the probability analysis and compare the output value to a predetermined threshold level.

18. The apparatus of claim 17, wherein the memory for storing instructions which, when executed by the one or more processors, further causes the one or more processors to determine the presence of the signal attenuation condition of the analyte sensor based on the comparison.

19. The apparatus of claim 18, wherein the predetermined threshold level is adjustable.

20. The apparatus of claim 12, wherein the memory for storing instructions which, when executed by the one or more processors, further causes the one or more processors to apply a probability distribution function to the determined sensitivity parameter to perform the probability analysis.
